

1. How a request becomes a row in SQLite

Every write in the app (register, create, resolve) follows the same shape.

- Validate handler
- Parameterize
- Call

2. Where is the authentication?

Authorization is enforced per action rather than as a whole.

- POST checks id before allowing an update, and the UPDATE checks the WHERE.

3. How search, filters and items load data

- GET/ - public no authentication
- GET/items/:id - public but personalized if logged in
- GET/me - authorization needed
